ii) Story Points

iii) Active Sprint

iv) Burndown Chart

2) Reflection Questions:

a) Did your estimations reflect the actual effort?

Ans: Mostly yes. Higher-complexity stories like Escrow Lock and Submit Inspection Report were both estimated at 5 points since they involved external system dependencies (Payment Gateway, inspection sign-off), while simpler stories like Place Order got 3 points. Sprint 1 showed that even 3-point stories took the full sprint window to finish, suggesting slightly optimistic estimation for a solo/individual task rather than a full team.

b) Was your backlog well-prioritized?

Ans: Yes — all 5 stories were marked High priority since they map directly to core FRs (place order, escrow lock, inspection, approval, payment release), which are all essential to the base transaction flow. In hindsight, a more useful split might have separated "must-have for MVP" (Place Order, Escrow Lock, Release Payment) from "important but slightly later" (Inspection Report, Dispute review), instead of marking everything uniformly High.

c) How did you simulate sprint align with your plan?

Ans: Sprint 1 didn't fully align — only 2 of 5 stories (8 of 19 points) were completed within the week, leaving 3 stories to roll into Sprint 2. Sprint 2 then completed all remaining work. This mirrors a common real-world pattern where initial sprints in a project are less predictable, and later sprints benefit from clearer scope and fewer unknowns.

d) What insights did the burndown chart give about your team’s capacity?

Ans: The Sprint 1 chart plateaued instead of reaching zero, showing that ~19 points were too much for one sprint at this pace — actual capacity was closer to 8-11 points/week. Sprint 2's chart, by contrast, burned down cleanly to zero, indicating the reduced, more realistic scope (11 points) matched actual capacity far better. This suggests future sprints should be planned around 8-11 points rather than the full 19-point backlog at once.
